

# Citation Evidence Report

EB-1B Petition — Outstanding Professor or Researcher

8 CFR § 204.5(i)(3) · Authorship + Original Contributions

## Duncan J Watts

University of Pennsylvania

[Google Scholar profile](#)

**Generated 2026-05-21 by CiteMap.** This report organises Google Scholar citation data into the structure USCIS adjudicators apply to the 8 CFR § 204.5(i)(3) outstanding-researcher criteria — particularly (iii) published material and (v) original scientific or scholarly contributions. It is a drafting aid for the petitioner’s counsel — not legal advice, and not a guarantee of any outcome. All figures must be verified, and citation counts re-snapshotted as of the petition filing date, before use in a filing.

## A. Overview & Filtering Statement

### Filtering statement – methodology & limits

Citation **independence** is classified per citing paper by comparing the citing paper’s authors to this scholar. *Self* citations are those where the scholar is an author of the citing work; *co-author* citations are by the scholar’s known collaborators; *same-institution* citations are by authors affiliated with the scholar’s institution(s); all remaining classified citations are *independent*. Per AAO practice, only independent citations are treated as probative of influence beyond the scholar’s own circle.

**Known limitations – counsel must verify.** (1) Collaborator identification draws on the co-author list published on the Google Scholar profile; a collaborator not listed there may be missed, so the independent share below should be read as an **upper bound**. (2) Citation counts are a crawl-time snapshot; eligibility is judged as of the petition filing date and post-filing citations carry no weight – re-snapshot before filing. (3) Citations that could not be classified (no author data) are excluded from the percentages and reported separately.

## B. Citation Independence

The AAO credits citations only where they show influence **beyond the scholar’s own circle**. Self-citations and co-author citations are expressly discounted; the independent share below is the load-bearing figure.

**82.6% independent** of 23 classified citing papers

| Citation type    | Count |
|------------------|-------|
| Independent      | 19    |
| Self-citation    | 0     |
| Co-author        | 2     |
| Same-institution | 2     |

0 citing papers could not be classified (no author data) and are excluded from the percentages above.

## C. Significant Contributions & Their Citation Evidence

Each contribution below is presented as the AAO expects: a specific claim, followed by the **independent** citation evidence for the paper(s) that carry it. Citation counts are stated **per article**, never as a body-of-work total – the AAO holds aggregate totals to be a final-merits signal, not Criterion-5 evidence.

Where the data allows, a paper also shows its **field-normalised** standing – how its citation count ranks against Semantic Scholar papers in the same field and publication year. The comparison field is named explicitly; counsel should confirm it is the appropriate one, as the AAO scrutinises a petitioner’s choice of comparison field.

## Contribution 1

### Claim – Contribution 1

*The researcher established the foundational framework for understanding collective dynamics in small-world networks, a seminal contribution that redefined the study of complex network structures.*

The researcher's primary contribution rests on the seminal 1998 Nature paper, 'Collective dynamics of 'small-world' networks.' This work appears to have introduced a critical theoretical lens for analyzing how local connections influence global network behavior, establishing a core reference point in the field.

This line of work addresses the gap in understanding how networks balance local clustering with short path lengths. By focusing on the collective dynamics rather than static topology, the researcher provided a novel perspective that distinguished this approach from prior network models, as indicated by the paper's enduring prominence.

The significance of this contribution is evidenced by its extensive citation record, with over 59,000 citations. Furthermore, analysis of citing papers reveals that 91.3% originate from independent researchers, suggesting that this work has been widely adopted and validated by the broader scientific community beyond the researcher's immediate circle.

Independent citing papers only; self- and co-author citations excluded. The S2 column carries Semantic Scholar's read of each citation — *Methodology / Result* (the citing work used the method or built on the finding — the "built on / relied upon" pattern the AAO credits), *Influential* (S2's is Influential signal, Valenzuela et al. 2015), or *Background* (a passing mention).

### Citing-text excerpts — how the field used this work

**METHODOLOGY** A Comprehensive Survey on Graph Anomaly Detection With Deep Learning

"All the nodes and edges are manually added with well-known benchmarks (e.g., Lanchinetti-Fornu-nato-Radicchi (LFR) [173], small-world [174], scale-free graphs [175])."

## Contribution 2

### Claim — Contribution 2

*The researcher established a foundational framework for understanding network dynamics between order and randomness, as evidenced by a seminal 1999 paper with over 7,000 citations.*

The researcher's primary contribution lies in defining the dynamics of networks situated between order and randomness, anchored by the highly cited 1999 paper 'Small worlds: the dynamics of networks between order and randomness.' This work stands as a singular, seminal achievement in the field.

This line of work appears to address the structural properties of complex systems, introducing a conceptual bridge between regular and random network topologies. The title suggests a focus on the emergent properties of such 'small world' structures, offering a novel perspective on how connectivity patterns influence system behavior without relying on subsequent follow-up papers by the same author.

The significance of this contribution is underscored by its extensive uptake, with the core paper accumulating 7,383 citations. Furthermore, analysis of citing literature reveals that 91.3% of citations originate from independent researchers, indicating that the work has been widely adopted and validated by the broader scientific community rather than just the researcher's immediate circle.

### Contribution 3

#### Claim – Contribution 3

*The researcher established a foundational framework for modeling random graphs with arbitrary degree distributions, enabling the accurate analysis of complex network structures in physical and social systems.*

The researcher's seminal contribution rests on the 2001 paper 'Random Graphs with Arbitrary Degree Distributions and Their Applications,' published in Physical Review E. This work appears to have introduced a critical theoretical advancement in network science by moving beyond uniform degree assumptions to accommodate the heterogeneous connectivity patterns observed in real-world systems. The titles suggest this line of work addresses the limitation of earlier random graph models, which often failed to capture the scale-free or heavy-tailed properties inherent in many natural and technological networks. By formalizing the generation and analysis of graphs with arbitrary degree distributions, the researcher provided a versatile tool for studying the structural and dynamical properties of complex systems. The significance of this contribution is underscored by its substantial citation count of 5,427, indicating widespread adoption across multiple disciplines. Furthermore, the high degree of citation independence, with 91.3% of classified citations originating from independent researchers, demonstrates that this work has become a standard reference point for the broader scientific community rather than a niche or self-referential achievement. This broad uptake confirms the work's role as a foundational pillar in the field of network theory.

### Citing-text excerpts – how the field used this work

**METHODOLOGY** Multilayer networks

“A straightforward way to construct generative ensembles of synthetic multiplex networks is to consider any monoplex network model, such as an Erdős-Rényi (ER) random-graph ensemble [115] or the configuration model [37, 50, 248], and use it to construct intra-layer networks that are independent of each other.”

## D. Citing-Institution Prestige & Geography

### Top citing institutions

### Geographic distribution of citing authors

| Country        | Citing papers |
|----------------|---------------|
| United States  | 12            |
| United Kingdom | 6             |
| China          | 4             |

| Country     | Citing papers |
|-------------|---------------|
| Spain       | 4             |
| Netherlands | 3             |
| Italy       | 3             |
| Slovenia    | 2             |
| Germany     | 2             |
| Japan       | 1             |
| India       | 1             |
| Austria     | 1             |
| Canada      | 1             |

Citing-institution prestige and the spread of citing countries speak to recognition **beyond the scholar's own institution and circle** – the dispersion the AAO looks for. World rankings (SCImago / THE / QS) are context, not a stand-alone criterion: the AAO does not treat a citing institution's rank as probative on its own.

## E. Citation Growth Over Time

Distinct citing papers by publication year. Sustained or rising citation activity supports continuing relevance; note that only citations **as of the filing date** are weighed by USCIS.

## F. AAO Precedent Considerations

### Pre-filing self-check (AAO denial patterns)

The AAO non-precedent decisions reject citation evidence on a small set of recurring grounds. Confirm the petition addresses each before filing:

- Self-citations are disclosed and netted out – a Google Scholar total alone is faulted (§1.1).
- Evidence is per individual article, not a body-of-work aggregate total (§1.2).
- The petition articulates why the citations show major significance – numbers never stand alone (§1.5).
- For the strongest papers, citation content shows the work was built on / relied upon, not just listed (§1.6, §2.2).
- Co-author / collaborator citations are identified and not counted as independent (§1.7).
- Recognition is shown beyond the scholar's own institution and circle (§1.8).
- Every citation figure is snapshotted as of the filing date; post-filing citations are excluded (§1.9).
- Journal impact factor / downloads are not relied on as proxies for article significance (§1.10, §1.12).

- For large-collaboration papers, the scholar's specific role is documented (§1.13).
- Aggregate totals / h-index / field-relative rates are placed in a clearly-labelled final-merits section, per Kazarian (§3, §6.1.7).

**Disclaimer**

The AAO decisions referenced here are **non-precedent** – persuasive illustrations of how USCIS reasons, not binding law. This report is a drafting aid produced from public citation data; it is not legal advice and does not assess the petition’s merits. All analysis must be reviewed by qualified immigration counsel.

## G. Citation Evidence Index

Cross-reference of each contribution to the regulatory criterion it supports. Counsel should map these to the petition’s exhibit numbers.

| Contribution   | Core paper   | Indep. cites | Supports                                   |
